

Inconsistencies in the role of the tongue root in phonological contrasts

Yana Outkin Tehya Banach Jonathan N. Washington
Swarthmore College

Central questions

- Is the role of the tongue root (TR) quantifiably consistent with previous studies?

Approach

- Develop quantifiable measure of contribution of various areas of tongue
- Test on various contrasts reported to use TR

Dolgan

	K	1.1e-10	0.00678	0.20871	1.00000

C^y/C^j: TB↓, TR↔ (not /K/)

Methodology

- Data from previous studies (cited)
- Wordlist tasks, in carrier phrases
- Annotated midsagittal tongue surface using UltraTrace (Murphy et al., 2020)
- frame closest to midpoint of Vs
- Plotted and analysed using ultrapolarplot (Outkin & Washington, 2024)
- Perpendicular rays intersect various areas of the tongue (mid TB, upper TR, etc.)
- Pairwise t-test between categories at intersections (adjusted for Type I error)
- Pairwise t-test compares maximum curvature (PMC) groups by calculating differences in distance to origin
- PMC comparison is a measure of difference in TB position

Discussion

- TR↔ significant factor in Russian C^y/C^j; does not hold for all pairs
- TR↔ significant factor in all Turkic V backness, but not for each individual pair in each language
- Some areas of TR significant for given contrast, while other areas not
- TR↔ significant for some rounding pairs, likely used to amplify perceptual distinctiveness beyond lip rounding

Future work

- More robust datasets
- Multiple speakers of the same language
- Extent of co-production vs TR independence
- Different analytical methods?
